McKechnie®
Transforming Aluminium

Extrusion Data And Tolerances

March 2025

Edition 9.1

Introduction

McKechnie®
Transforming Aluminium

McKechnie® Aluminium is one of Australasia's leading aluminium specialists, manufacturing an extensive range of standard extrusions, customer exclusive extrusion and providing world class aluminium fabrication services.

McKechnie® Aluminium is the only Australasian manufacturer who provides a full "foundry to fabrication" offer with service levels you can only get from a local supplier. We are proud of our 60 years in business and the unmatched level of technical expertise and market experience this has given us.

The range of standard shapes in this catalogue will meet most customers' requirements, however if you have an application or design that is unique to you, we can easily provide a custom product or solution specifically for you.

To make it easy for you to find the section you are looking for, this catalogue has been organised into product groups and has a full index of sections and page numbers on page 209.

Design:

All sections shown in this catalogue are McKechnie® Aluminium standard designs and available to all customers. These designs are owned by McKechnie® Aluminium and protected by copyright.

Availability:

Products in this catalogue are subject to minimum production runs and normal production lead times at time of order. Smaller quantities of these extrusions can be supplied ex-stock via our McKechnie® Direct channel with next day delivery nationwide.

Additional Sections will continue to be added to our range so visit our website www.mckechnie.co.nz for the latest version of this catalogue or call us to ask about any sections not listed.

Surface Finishing, Fabrication and Pricing:

Please contact your nearest McKechnie® Aluminium sales outlet (details on next page). We can also offer surface-finishing options, powder-coating and anodising, and such services as precision cutting, punching, drilling via our Fabrication operation.

Technical Data:

The alloys available and extrusion tolerances are listed in the front of this catalogue. This information is a guide only. Please contact us if you have any questions on alloys or tolerances not covered in this catalogue.

- Drawings individually listed are full-scale unless endorsed otherwise.
- All sharp corners are slightly radiussed.

This catalogue is available both wholly and in part through Electronic Communication. Access information available on request.

McKechnie®
Transforming Aluminium

ALUMINIUM IN ARCHITECTURE

The growth of aluminium in architecture in New Zealand has been quite dramatic in recent years. When McKechnie® Aluminium first commenced extruding aluminium in 1958 in this country, domestic windows, patio doors, and generally domestic components of aluminium were virtually unknown. Commercial window applications were in their early stages while the interiors of commercial buildings contained virtually no aluminium. Partitions, for example, were almost entirely of solid-wall construction.

Since then we have reached the stage where aluminium is virtually standard in many of these areas and its proportional penetration continues to grow. Aluminium is still the 'modern' metal. It lends itself well to the slender, open appearance which is evident in many buildings. Commercial building construction has passed through a number of phases in which the trend in the sixties was towards curtain-wall construction, whilst now there is greater emphasis on the use of individual windows and various building panels.

Internally, demountable partitioning is now almost universal, using hollow framing members, often aluminium extrusions designed to take electrical and other services. These partitions can be easily moved according to demand from time to time, thus facilitating the most effective use of ever increasingly expensive office accommodation.

One of the major areas of aluminium penetration has been in windows and doors, both domestic and commercial, and in shop fronts. Aluminium gives the architect almost unlimited freedom in setting out his window requirements and allows him to specify profiles which satisfy his needs and offer him a completely draft-proof window, permanent in its proof against infiltration. Good provision of weather stripping is no problem with extruded sections and is generally used.

Aluminium in window and door frames in the various finishes available provides an excellent blend, often with striking effect, with timber paneling, bricks, stone, and most of the decorative building materials available. Aluminium has proved itself eminently suitable as a metal for the manufacture of windows, doors, shop fronts and similar installations since it can be formed and fabricated in ways hitherto commercially impossible for both wood and steel. As a result, various new forms of fenestration have been made economically possible.

High-purity aluminium is soft and ductile, and strength and hardness are acquired by the addition of various alloying elements such as magnesium, silicon, manganese and copper. Aluminium products are either wrought or cast, depending on whether their shape results from mechanically working the metal or from casting molten metal. Wrought alloys are used to produce extruded shapes, forgings and sheet products while cast alloys are used for the production of ornamental components and the mass-production of standard parts.

Aluminium is light in weight, being, for example, three times lighter than steel. It has excellent strength and durability. Properly installed, aluminium can provide years of dependable service, with its high, inherent resistance to atmospheric corrosion. Unlike many other metals, aluminium does not cause unsightly weathering stains on other materials. It responds well to various forming operations, cutting, welding and forging, and thus offers considerable flexibility in its use. It can be joined by all commonly-used methods such as welding, and use of adhesives and mechanical fasteners. It is non-sparking and non-magnetic. Aluminium has certain properties which require the architect's attention in using it most effectively.

The selection of an alloy for a particular application should be based on a careful evaluation of design requirements by way of mechanical properties and finishing characteristics. McKechnie® Aluminium alloy 6060 has proved highly successful for extruded sections for the manufacture of windows, doors and architectural joinery in various finishes. Other alloys can be used for certain specific extruded applications.

Aluminium extrusions have a comparatively high coefficient of expansion which is 0.000023mm per mm length of extrusion per 30° C. A length of aluminium extrusion 6 metres long will expand over 4mm when the temperature rises 30° C. When designing, especially building design, provision should be made for expansion and contraction caused by temperature changes. Thermal expansion is particularly important where aluminium extrusions are used with other materials which have different expansion rates.

Practically all aluminium alloys can be welded. For fusion welding the inert gas-shielded arc methods are now used almost exclusively and offer the advantages of high welding speed and freedom from flux problems.

McKechnie®
Transforming Aluminium

THE NATURE AND BENEFITS OF ANODISED ALUMINIUM

The capacity of aluminium to respond to anodising, the most familiar of finishes, makes aluminium a most important metal in a quite fundamental way. The fact that aluminium can take on this attractive, durable and tough-wearing finish makes it possible to exploit its strength and lightness in a large number of applications, particularly in building construction. Anodising essentially is an induced thickening of the natural protective oxide film on the metal's surface. It is a conversion of the parent metal and thus is not a 'coating' in the usual sense.

Unless severely deformed or stressed by excessive thermal movement, the anodic film will not chip, peel, or crack. With conventional sulphuric acid anodising, the alloys usually anodised produce a clear, hard, and extremely corrosion-resistant film capable of being coloured. The functional and decorative potential this confers on the metal is widely exploited in applications ranging from building components to domestic cookware.

Variations of the conventional electrolyte composition and process variables produce anodic coatings of distinctive functional properties. Thus, very hard anodic films are developed to provide abrasion resistant surfaces on gears, pistons, bearings, and similar components.

Anodic films are coloured by a variety of methods. Conventional sulphuric acid films are microscopically porous, and organic or inorganic dyes and pigments may be incorporated and sealed in the film. The more durable coloured films necessary in exposed environments are more usually produced integrally with the evolution of the anodic layer and are quite permanent.

Whether clear or coloured, it is important that designers understand the essential nature of anodising. Inevitably, the anodic film reproduces the physical nature of the original metal surface. Not only does this mean that any mechanical finish applied previously to the surface will be clearly evident, but even the characteristics of different metal forms will persist. Thus, an extruded element and a sheet element, if colour anodised to the same specification and placed together, will show an apparent colour difference due solely to minor but characteristic differences in surface profile peculiar to the mill process which produced them.

The basic anodising process consists of a suitable chemical pre-cleaning dip, followed by etching in a caustic soda or acid base solution, anodising electrolytically in a sulphuric acid or other solution, and finally sealing to preserve the anodised surface. The anodised surface is in fact an inert, and therefore a protective film of aluminium oxide. The thickness of the aluminium oxide "anodised" coating can be varied by processing time. The depth of anodised coating may be varied according to application.

- 25 Micron is recommended for heavy duty external permanent architectural applications where little deterioration can be tolerated.
- 15 Micron is recommended for the majority of ordinary architectural requirements.
- 10 Micron is suitable for internal applications, and outdoor applications where cleaning is very frequent, for example, caravan trim.

The above figures when specified are minimum figures, and film thickness is checked on a batch basis by electronic means.

Colour finishes are checked for colour match against standards.

Cleaning is desirable if the fine finish of anodized aluminium is to be preserved. Deterioration of the anodic film occurs mainly as a result of grime deposition and attack by contaminated moisture, which in a coastal environment contains chlorides and in an industrial or urban environment contains sulphur compounds. Deposited grime absorbs contaminated moisture like a sponge and holds it against the anodized surface; this permits the attack to proceed thereby damaging the film, which cannot be restored without removal. Regular cleaning is desirable, the frequency depending on accessibility and the severity of the environment. In a rural atmosphere where grime deposition and pollution of the atmosphere are at a minimum, cleaning may not be needed more frequently than every six months in order to remove deposits and restore the appearance.

In industrial and marine environments more frequent cleaning, e.g. monthly, is necessary and the maximum period between cleanings should never be more than three months. Under the worst conditions involving heavy grime deposition and atmospheric pollution by both sulphur compounds and chlorides, even more frequent

McKechnie®
Transforming Aluminium

cleaning is advisable if deterioration of the anodic film is to be prevented.

As a general rule, it could be assumed that with outdoor applications anodized components should be cleaned with the same frequency as windows, using the same materials and techniques.

Where an anodized surface has been neglected, it is sometimes possible to effect restoration by the use of solvents such as kerosene or mineral turpentine in conjunction with a mild household abrasive using a soft cloth. The use of harsh abrasives will damage the film beyond repair.

HANDLING AND STORAGE OF ALUMINIUM

All fabricators and other manufacturers who use aluminium as a raw material face the need to handle and store it. Aluminium can, with very little care, be kept in good condition. It has a high natural resistance to the corrosive conditions normally encountered during transport and storage. The principal conditions against which it is necessary to guard are those likely to cause surface abrasion and water stains.

Every effort is made at McKechnie® Aluminium to pack aluminium extrusions in a way which avoids surface deterioration during transport. The method of packing minimises damage due to flexing and twisting, while paper and spiral plastic wrapping protects ultimately visible surfaces. The method used has proved highly successful in New Zealand for many years.

Nevertheless, it is advisable to inspect all loads as soon as possible after arrival to ensure that damage has not in fact been caused by excessively severe conditions during transport.

When transport marks are present they take the form of scratches or general abrasion, or a condition resembling black cinders embedded in the metal. The latter results from mechanical abrasion followed by oxidation of the abraded areas. The main disadvantage of such a damaged surface is its unsightliness and its effects on finishing operations. It is not important if the damaged face is ultimately not visible. Surface damage does not affect mechanical properties.

Water stains are non-metallic in appearance and while usually whitish, may appear iridescent, depending on the alloy or degree of oxidation. They are caused by entrapped water between adjacent surfaces of closely stacked metal. The purer aluminium alloys are more resistant to water stain, while the condition seems most pronounced on those alloys having a high magnesium content. Water stain is superficial and mechanical properties of the metal are not affected.

Should a shipment of aluminium arrive in a wet condition, it should be immediately thoroughly dried before storing. Drying may be by evaporation in air or by means of dry air currents. Very wet metal should first be wiped down.

When a metal is dried as above within a short period of its becoming wet, no stain will result. If there is a slight stain and the metal is dried, the stain will not develop further.

Aluminium, once dry, should not be stored near such obvious water sources as steam and water pipes and should be kept a reasonable distance from open doors and windows.

Probably the most troublesome cause of water stains is condensation. It may be prevented by avoiding conditions where the temperature of the metal drops below the dew point of the surrounding air, or, conversely, where the moisture content of the air increases enough to take the dew point above the metal temperature. It is thus important that there should not be a sudden fall in temperature or increase in humidity in the place of storage.

Architectural extrusions, as packed by McKechnie® Aluminium, will keep well in their packs for a reasonable time so long as atmospheric conditions do not vary too greatly as described above. However, the packs should not be stored outside since they are not designed to withstand exposure to weather and the variations which occur outside.

When cold metal is brought into a warm shop area it should be left undisturbed, in its pack until the aluminium has been brought up to room temperature. This may take 36 to 48 hours. Opening the pack before the metal

McKechnie®
Transforming Aluminium

has reached room temperature may result in water stain from the condensation which forms on the cold metal.

When the surface of a stain is reasonably smooth and it is quite superficial, appearance can be improved by mechanical or chemical treatments. Scratch brushing with "Scotchbrite" is effective in removing water stains. A suitable chemical dip which does not produce undue etching is an aqueous solution containing 10% sulphuric acid and 3% chromic acid at 82° C.

In storing aluminium it is desirable to avoid contact with other metals which sometimes cause scratches or other marks. The use of shelving or racks faced with dried wood is recommended. Aluminium should also be kept away from caustics, nitrates, phosphates and some acids.

When large quantities of metal are used continuously the oldest stock should be used first. Stock on hand should be checked from time to time and this will help to prevent any serious corrosion.

SOME CORROSION ASPECTS OF ALUMINIUM

All materials of construction have individual characteristics which call for special consideration in design, fabrication and installation. Aluminium is no exception and needs to be installed in proper fashion if best use is to be made of it and maximum service is to be obtained.

Most of the standard aluminium alloys supplied for architectural and structural applications (e.g. McKechnie® Aluminium 6063 and 6060, 6061 etc.) perform very satisfactorily in normal exposed positions. The immunity of aluminium to the atmosphere arises from the protective nature of the oxide film which acts as a barrier to corrosion. For many purposes, decorative as well as protective, the naturally formed oxide film is thickened by anodising and the protective value of the oxide film is thus considerably increased. The comments which follow apply mostly to unanodised aluminium.

In every climate where the atmosphere is at all humid, building and engineering materials undergo some chemical change with the passage of time and are subject to some form of corrosion.

Specific Modes of Attack

Several characteristic modes of attack on aluminium may be distinguished. In the presence of specific substances simple chemical attack may occur. Attack of aluminium by very weak corrosive solutions, such as contaminated rain water, is often insignificant if not prolonged, but it becomes important if circumstances cause the solution to be retained in contact with the metal. Sodden timber lying flat on aluminium, or moist insulation in contact with it are examples of absorbent material acting with a poultice effect. The corrosive solution is held continually in contact with the metal and rapid attack may result.

Crevice effect describes the acceleration of attack when moisture is lodged, for example, in the crevices of riveted or bolted joints in a structure, or when moisture is held by surface tension between the aluminium surface and some object lying against it.

It is possible for a building material when wet to liberate some specific chemical which can corrode aluminium used in the structure. This is corrosion by moisture exudation. Those which may attack aluminium are chiefly from alkaline building materials such as freshly-set plaster, mortars and cements and also acids from certain timbers when wet or unseasoned.

Corrosion of aluminium may be accelerated through contact with another metal in moist or wet conditions and this is known as galvanic corrosion. The two metals, together with water present, constitute a cell, causing a small electric current to flow and leading to corrosion of the less noble metal.

For example, when copper or steel is in contact with aluminium under above conditions aluminium will corrode but when zinc (galvanised surface) is in contact with aluminium then zinc will corrode.

Stainless steel and aluminium form an exception because the combined resistance of the two protective films impedes the current flow, thus reducing galvanic action.

McKechnie®
Transforming Aluminium

General Means of Preventing Corrosion

The methods of preventing the corrosive effects just described really amount to the avoidance of the conditions which lead to them. Often it is impossible to avoid all the conditions but at least one form of preventive action can be taken and this will be adequate.

As moisture or liquid is essential to corrosion, the exclusion of moisture prevents its occurrence, but the choice of method depends on the nature of the problem. Poultice effect may be tackled by a moisture-proof barrier applied to the aluminium surface. Crevice effect is eliminated if the crevices are filled or stopped. Sometimes the trouble can be countered by designing a component to eliminate moisture traps, or making all contacting components of aluminium and eliminating particular contaminating constituents in, say, water which enters the crevice.

Mastics and putties (linseed oil) are satisfactory in contact with aluminium. Putties give good adhesion to aluminium where sound installation practice is followed, for example, by allowing the metal surface to weather, thus forming a key or, alternatively, by applying an etch primer. The choice of thermal insulating materials for use with aluminium must allow for condensation when the system cools below the dew point. This is because some insulation's contain chloride or alkali which can be leached out and may give rise to corrosion.

For detailed information dealing with the effects of specific materials and chemicals on aluminium the McKechnie® Aluminium Technical Services Department will be pleased to offer advice. There are many forms of assembly where water may be trapped in pockets because of exposure to the weather or condensation. There are several ways in which an accumulation of water may be prevented. For example, drainage holes may be drilled or complete drainage may be assisted by avoiding completely horizontal surfaces. When designing it is important to bear in mind, however, that surface tension tends to keep small holes filled with water until it evaporates. The size of the holes is therefore important.

When joining aluminium by bolts or studs to other metals it may be possible to use non-absorbent inserts of plastic, rubber or neoprene.

Corrosion may be prevented sometimes by adding inhibitors to oppose the reaction of the active corroding agent. Zinc chromate contained in priming paints for aluminium acts as an inhibitor.

Aluminium in Contact With Other Materials

A number of specific materials commonly encountered in building construction are now considered for their corrosion influence on aluminium. These fall into three main categories, iron and steel, non-ferrous metals and non-metals.

(a) Iron and Steel

In contact with structural steel, aluminium suffers attack when a good electrolyte is present, such as sea water or condensed moisture in industrial areas. Several treatments can be applied to the steel such as metal spraying, galvanising, zinc or cadmium plating, painting with zinc-rich paints and so forth.

(b) Non-Ferrous Metals

Reference has already been made to the main non-ferrous metals likely to be encountered in building construction where contact can exist with aluminium.

Contact with copper and its alloys must be avoided and chromium or cadmium plating, for example, is a satisfactory means to prevent this.

Frequently corrosion between aluminium and other metals can be avoided by lacquering, painting or sealing joints so that moisture is excluded.

(c) Non-Metals

Aluminium alloys used for building purposes have good corrosion resistance to concretes, mortars, plasters or fibre cement products. However, when freshly mixed some of these materials release traces of alkaline ducts which may be sufficient to stain aluminium. Splashing of these products onto aluminium, while not sufficiently corrosive to affect strength, does produce an unsightly, stained appearance. Contact with stone or brickwork, particularly when more open-grained and wet, can have a similar effect. Some separation by spacers at the joints should be effected.

In very many applications, particularly indoor, contact between aluminium and timber has been successfully used. However, some more strongly acid timbers in damp environment can cause corrosion. Plastics are virtually without action on aluminium in most conditions of service. Rubber is also without action on aluminium. Adhesives are available for bonding aluminium. Suitable adhesives should not contain in excess of 0.1% chlorides (e.g. NaCl).

McKechnie®
Transforming Aluminium

ALUMINIUM SURFACES – CLEANING IS IMPORTANT

Aluminium has a natural beauty and lustre. Its surface can be treated in various ways to produce different effects, while in the hands of the skilled architect it lends itself to some excellent effects and variations, and contrasts with other materials.

For this reason and because aluminium is so well-proven in service, it is now by far the most common material for exterior work such as windows, doors, curtain walls and shop fronts.

The surface finish of aluminium can be spoiled by improper care and the purpose of this note is to summarize the methods of maintaining aluminium after proper erection on site. Usually this care is no more than periodic cleaning, on a similar basis to which the glass in the windows is cleaned, and it is often merely lack of appreciation of this fact or which can spoil the effects so proudly established in the first place.

Anodising substantially enhances appearance and renders the surface more resistant to various forms of attack and facilitates cleaning and maintenance.

The Architectural Aluminium Fabricators' Association of New Zealand has published a good guide to Design and Specification and this deals with all aspects of design and use, care and maintenance.

Our aim here, rather briefly, is to highlight the cleaning aspect since it applies to so many users of architectural aluminium products.

Grime which causes deterioration cannot be pre-vented from settling on exposed surfaces. If cleaned reasonably frequently then the mildest methods of washing will produce satisfactory results.

There are many ways to clean aluminium, from using plain water to harsh abrasives. The type of cleaning that should be used is governed by the finish, degree of soiling, and the size, shape and location of the surface to be cleaned.

The mildest method possible should be used, particularly for aluminium which has been anodised.

The following cleaning materials and procedures are listed in ascending order of harshness. The mildest treatment should be tried on a small area and if not satisfactory only then should the next be examined.

- Plain water.
- Mild soap or detergent.
- Solvent cleaning, e.g. kerosene, turpentine, white spirit.
- Non-etching chemical cleaner.
- Wax base polish cleaner.
- Abrasive wax.
- Abrasive cleaner.

After applying the cleaner, aluminium should be washed down thoroughly and dried with a clean cloth to prevent streakiness.

There should be no concentration of the cleaner at the bottom edges of the aluminium.

If using proprietary cleaners the maker's recommendation should be obtained and followed carefully.

If abrasives are used then the appearance of the aluminium finish may be altered. If there is a grain in the finish then cleaning should always be with the grain.

Once the condition of the surface requires the use of abrasive or etching materials it is advisable to consult either cleaning specialists, or the McKechnie® Aluminium Technical Service Department will be pleased to offer advice.

When all other methods fail it may be necessary to resort to heavy duty cleaning. This involves the use of cleaners containing strong etching chemicals or coarse abrasives.

Regular cleaning of the surface with the correct materials will ensure an everlasting product.

McKechnie®
Transforming Aluminium

COMPATIBILITY WITH COMMON BUILDING MATERIALS

The use of aluminium in building construction involves its close association with many other materials. Aluminium is compatible with most, but there are a few which require some special attention. The table below summarises the more common building materials with which aluminium may be associated and the treatment required to ensure lasting success.

MATERIAL	COMPATIBILITY	TREATMENT
Iron and Steel	In exposed applications there will be attack	Coat steel surface with a resin-based aluminium or zinc pigmented paint.
Galvanised Steel	Satisfactory provided the atmospheric conditions are not likely to break down the zinc coating	No protection required. Preferable to use soft aluminium for flashing.
Lead	Very little action	Must be plated with nickel and/or chromium.
Copper & Brass	Severe corrosive action	Run-off water should always drain from aluminium - never from copper to aluminium.
Cadmium Plate	Satisfactory provided the plating is of high quality.	
Nickel/Chrome Plate	Satisfactory provided the plating is unbroken.	
Stainless Steel	Satisfactory	
Damp or Unseasoned timber	Not satisfactory	Timber must be primed with zinc chromate undercoat and sealed with a suitable protective paint
Plaster, Terrazzo, Cement	Until set severe corrosive action occurs	Exposed faces of aluminium must be protected.

TEMPER DESIGNATIONS

DESIGNATION	DESCRIPTION
F	As extruded only.
T1	Solution treated and quenched from an elevated temperature as part of the extrusion process and naturally aged.
T4	Solution treated and quenched from an elevated temperature as part of the extrusion process and naturally aged. Applies to products that are not cold worked, or where the effect of cold work is not recognised in applicable standards.
T5	Solution treated, cooled from an elevated temperature as part of the extrusion process and then artificially aged to substantially improve mechanical properties.
T52	A temper satisfying T5 requirements with improved formability
T6	Solution treated, cooled from an elevated temperature as part of the extrusion process and then artificially aged to give maximum mechanical properties.

Note: A second or third digit may be added to designated tempers. This indicates a variation in the production process has been applied to alter the final characteristic of the product, i.e. to achieve improved ductility etc.

McKechnie®
Transforming Aluminium

Extrusion Data

SURFACE FINISH DESIGNATIONS

FINISH	DEFINITIONS
Structural	This is not controlled for uniformity of appearance. Rod, bar and solid shapes are supplied in this finish unless otherwise specified.
Architectural	A controlled finish of substantially uniform appearance, buffing will not produce a finish free of die-lines unless a preliminary grinding or sanding operation is employed. This finish is normally satisfactory for exposed surfaces of any architectural application, other than feature components and is applied to visible surfaces of each shape nominated by the purchaser.

MAINTENANCE & CARE OF POWDERCOATED PRODUCTS

Powder coating is probably one of the most durable colour coatings available for a wide range of products and uses. However, to obtain the very best results in overall finish and in longevity, correct product handling and maintenance is essential.

In many cases, powder coated extrusions require the use of sealants as part of the fabrication process. Many sealant manufacturers recommend the cleaning of powder coated surfaces prior to the application of sealants. Sometimes a primer may be required. The selection of the solvent used is critical. Some can cause irreparable harm to the Powder coated surface. Advanced colour and gloss loss can appear in a short space of time if a harsh solvent is used. Suitable cleaning products include: White Spirits, Methylated Spirits, Turpentine, Ethyl Alcohol, Isopropanol. These solvents are mild and readily available.

Do not use Acetates, Dulon Thinners, Methyl Ethyl Ketone (MEK) or Petrol products. Highly acidic, alkali or alcohol based cleaners are not recommended either.

Ensure regular maintenance

As with many coated surfaces, regular maintenance will extend the life of the surface and retain its appearance. Cleaning should be conducted routinely at three monthly intervals and six months should be considered the longest interval. In industrial or marine locations particular attention should be paid to regular maintenance due to the harsher atmosphere.

- Clean with a dilute solution of mild liquid detergent. Avoid excessively hot solutions.
- Use a soft bristle brush. Do not use abrasive tools on the coating. After cleaning, rinse thoroughly with fresh water. Ensure that areas that are not normally exposed to rain are washed and rinsed also.
- Do not use strong solvent type cleaners. Where the use of solvent is required, such as cleaning paint spills, use nothing other than Methylated Spirits. Ensure that the contact time is as short as possible, and rinse the solvent cleaner thoroughly from the surface with copious amounts of drinking quality water.
- It is strongly recommended that a small test area be checked first, to ensure that no damage will occur to the whole area.

REFURBISHING POWDER COATED PRODUCTS

All surfaces eventually degrade on prolonged exposure to the elements. Change of colour, loss of gloss and some chalking may eventuate after time. A number of restoration techniques are possible.

These will depend on the circumstances, the life expectancy of the refurbishment and the approach may vary between domestic and commercial applications.

Domestic Refurbishment:

Polish with a high quality automotive cream polish in accordance with the manufacturers instructions. This will both clean and protect the surface. Avoid polishes which also contain cutting compounds, unless the surface is extremely weathered.

For badly scratched surfaces use a dab stick or aerosol can with colour matched paint. These are available from your local aluminium window and door fabricator.

Alloy 6060

McKechnie®
Transforming Aluminium

PROPERTIES AND SPECIFICATIONS:

Machinability C Average

Weldability

- Gas A Generally weldable by all commercial procedures and methods.
- Arc A
- Resistance, Spot & Seam A

Brazeability A Generally weldable by all commercial procedures and methods.

Typical Applications

Structural applications, transport and marine, extrusions for portable ladders. Used for applications requiring greater strength than 6063 and 6106 alloys.

Notes:

- 1) Chemical compositions are referenced in AS/NZS 1866. Single figures are maximums.
- 2) Mechanical properties and ratings for T5 tempers are specified in AS/NZS 1866. (Note McKechnie® internal designation T6 temper).
- 3) Thickness is defined as the diameter of solid rod or the wall thickness or the equivalent major solid cross section.
- 4) Yield is based on 0.2% Proof Stress.
- 5) Elongation is based on 50mm test parameter.
- 6) Ratings A through E are relative ratings in order of merit for the hardest temper (A = Excellent E = Poor).

Consult McKechnie® Aluminium Technical Services Department if further information is required.

Important Information on Order & Pricing Requirements

ORDER REQUIREMENTS

- # - A hash symbol alongside a section number indicates sections that are subject to specific MOQ's (minimum order quantities) are POA (price on application) and require different supply tolerances. For these sections, please contact your key account manager.
- * - A star symbol alongside a section number indicates that some close or special tolerances apply.
- + - A plus symbol along side a section number indicates that the section is available to order in 6.0m length only.

PRICE EXTRAS (Added to base metal rate)

- Alloy extras may be applicable for alloys other than 6060.
- Quantity extras may be applicable for orders of less than 250kg.
- Length extras may be applicable for lengths less than 3m or over 6.5m.
- Packaging cost extras may be applicable where packs smaller than our minimum pack size of 150kgs are requested.
- Size and shape extras may be applicable for shapes that are large and / or complex.

Note: This catalogue is revised regularly. The list of sections it contains do change and availability of any given section can only be confirmed at the time of order placement and order confirmation.

MANUFACTURING TOLERANCES AS/NZS 1866:1997

CLASSIFICATION OF HOLLOW EXTRUDED SHAPES

Hollow extruded shapes are classified as follows:

- (a) Class A
A hollow extruded shape having a single void with no internal or external protrusions, and which is greater than 15 mm in diameter or 177 mm^2 in area. The void may be round, square or rectangular, provided that the width/depth ratio is less than 5:1. It has uniform wall thickness except that a non-uniform wall is allowed at corners having internal or external radii up to 7.5 mm.
- (b) Class B
A single void hollow extruded shape other than a Class A shape, or a solid shape incorporating a single semi-hollow area classified as a hollow.
- (c) Class C
A hollow extruded shape having two or more fully enclosed voids.
- (d) Class D
Any hollow shape that incorporates a semi-hollow area, or any solid shape that incorporates multiple semi-hollow areas that are classified as hollows
- (e) Yacht mast extrusion
A hollow or solid extruded shape, which is basically round or elliptical in section and which incorporates a sail track or has provision for a sail track, used in the manufacture of masts and booms for yachts.

DIAMETER, WIDTH AND DEPTH TOLERANCES FOR CLASS A HOLLOW SHAPES

Specified dimension		TOLERANCE, PLUS OR MINUS	
		Round tube	Square and rectangular hollows
		Allowable deviation of diameter from specified diameter	Allowable deviation of width or depth from specified width or depth. (see Note)
Column 1		Column 2	Column 3
	≤ 25	0.5	0.5
>25	≤ 50	0.7	0.7
>50	≤ 100	0.8	0.9
>100	≤ 125	1.3	1.2
>125	≤ 150	1.3	1.4
>150	≤ 180	1.9	1.7
>180	≤ 200	1.9	1.9
>200	≤ 220	2.6	2.2
>220	≤ 250	2.6	2.4
>250	≤ 280	3.2	2.7
>280	≤ 330	3.8	2.9

Table 1

Note: For a rectangular hollow as shown in the diagram, the tolerances are determined as follows:

- (a) The tolerance for the width, A, is the value in Column 3 for a dimension equal to the depth B.
- (b) The tolerance for the depth, B, is the value in Column 3 for a dimension equal to the width A.

McKechnie®
Transforming Aluminium

Tolerances

WALL THICKNESS TOLERANCES FOR CLASS A HOLLOW SHAPES

Specified wall thickness (see note)		Allowable deviation from specified dimension for round tube, square and rectangular hollows, plus or minus	
		Circumscribing circle diameter (CCD) ≤125	Circumscribing circle diameter (CCD) >125
>1.0	≤1.5	0.2	0.25
>1.5	≤2.5	0.25	0.25
>2.5	≤3	0.30	0.30
>3.0	≤4	0.35	0.35
>4.0	≤5	0.40	0.45
>5.0	≤6	0.50	0.55
>6.0	≤7	0.60	0.65
>7.0	≤8	0.65	0.75
>8.0	≤9	0.70	0.85
>9.0	≤10	0.70	0.95
>10.0	≤11	0.75	1.05
>11.0	≤12	0.80	1.15
>12.0	≤13	0.85	1.25
>13.0	≤14	0.90	1.35
>14.0	≤15	0.95	1.45
>15.0	≤20	1.00	1.55
>20.0	≤25	1.25	1.65
>25.0	≤40	1.50	1.75

Table 2

Note: When the dimensions specified are outside and inside, rather than wall thickness itself, the allowable deviation of the wall thickness applies to the mean wall thickness. The mean wall thickness is the average of the maximum and minimum measured wall thickness, when measured at the ends of the cut length.

Tolerances

STRAIGHTNESS TOLERANCES FOR ALL EXTRUDED PRODUCTS

Alloy and Temper	ALLOWABLE DEVIATION FROM STRAIGHTNESS, D, MM	
	In any length ≤ 300 mm	In total length of L, m
6106-T5 & T6	0.2	0.7 L
6063-T5 & T52	0.2	0.7 L
6060-T5 & T52	0.2	0.7 L
All other alloys and tempers	0.6	2.0 L

Table 7

FLATNESS (FLAT SURFACE) TOLERANCES FOR ALL EXTRUDED PRODUCTS

millimetres

Surface width, W	ALLOWABLE DEVIATION FROM FLAT, D,	
	Solid shapes	Hollow shapes L, m
≤ 25	0.1	0.15
> 25	$0.004W$	$0.006W$
In any 25 mm width	0.1	0.15

Table 8

ANGULARITY TOLERANCES FOR ALL EXTRUDED PRODUCTS

Allowable deviation from specified angle
± 2 degrees

Table 9

TOTAL TRANSVERSE FLATNESS TOLERANCES FOR CLASS C HOLLOW SHAPES

Total width, W		Allowable deviation from flat, D
	≤100	0.004 W
>100	≤150	0.005 W
>250		0.006 W

Table 10

CONTOUR (CURVED SURFACE) TOLERANCES FOR SOLID SHAPES AND CLASS B, C AND D HOLLOW SHAPES

ALLOWABLE DEVIATION FROM SPECIFIED CONTOUR
0.15 mm per 25 mm of chord length (Minimum tolerance = 0.15 mm)

Table 15

CORNER AND FILLET RADII TOLERANCES FOR ALL EXTRUDED PRODUCTS

Specified radius mm	Allowable deviation from specified radius
≤ 5	± 0.4 mm
> 5	$\pm 10\%$

Table 16

TOLERANCE FOR SQUARENESS OF CUT ENDS FOR ALL EXTRUDED PRODUCTS

Allowable deviation from square
1 degree

Table 17

YACHT MASTS

LEGEND:

T = Wall thickness

D = Depth

W = Width

G = Gap dimension

Refer to McKechnie® Aluminium for tolerances
